FORESTRY EXPERIMENT STATION

## NOTICE TO USER

This Mississippi Agricultural and Forestry Experiment Station Information Bulletin is a summary of forage research intended for the use of colleagues, cooperators, and sponsors. The interpretation of data presented herein may change after additional experimentation. Information included herein is not to be construed either as a recommendation for use or as an endorsement of a specific product by Mississippi State University, the Mississippi Agricultural and Forestry Experiment Station, or the Mississippi State University Extension Service

This report contains data generated as part of the Mississippi Agricultural and Forestry Experiment Station. Joint sponsorship by the organizations listed on Page 12 is gratefully acknowledged.

Trade names of commercial and public varieties tested in this report are included only for clarity and understanding. All available names (i.e., trade names, experiment code names or numbers, chemical names, etc.) and varieties, products or source seed in this research are listed on Page 12.

# Mississippi Cover Crop Variety Trials, 2019 

## INTRODUCTION

Many seed companies and clientele that specialize in forage crops have expanded some of their products to act as cover crops in mixtures or in monoculture. Typically, cover crops are planted before a grain crop to stabilize residual nitrogen or to increase soil nitrogen content (via legumes) for the following crop. In theory, a cover crop can be any plant established for this reason and even include volunteer weeds. However, the most desirable characteristics of a cover crop can include
rapid growth to increase incorporation tonnage, lack of competition with the targeted grain crop, low cost to establish, ability to increase N and organic matter in the soil, and effectiveness at providing ground cover during the winter. Some legumes can provide enough nitrogen through "fixation" to feed the following grain crop, while some grass crops can provide an allopathic effect, as well as increasing soil organic matter, which benefits the following crop performance.

## PROTOCOL

Varieties of several cover crop species were evaluated in 2019 as part of Mississippi Agricultural and Forestry Experiment Station (MAFES) small-plot trials. Entries were provided by seed companies as well as breeding programs at state universities. All entries from privately owned companies are tested on a fee basis. Selected varieties that are publically or commercially available may be added by the MAFES forage variety-testing program as a reference check for comparison purposes. In addition, varieties of interest may also be added when applicable. Testing during 2018-19 was conducted at the North Mississippi Branch Experiment Station in Holly Springs, Leveck Animal Research Center Forage Unit on the Mississippi State campus, and Coastal Plain Branch Experiment Station in Newton.

The cover crop trial was planted at all locations in the first week of October 2018. Plots were 6 feet by 10 feet and planted using a precision cone seeder on a prepared seedbed. Trial design was a strip plot replicated four

Table 1. Recommended seeding rates for cover crops.

times with harvest date representing a single strip. Recommended seeding rates were used and are presented in Table 1. Individual strips were harvested March 15 and April 1 to best represent cover-crop incorporation before corn production in Mississippi.

At harvest, a weed suppression rating was performed using a $1-10$ rating with 1 equal to no weed suppression and 10 equal to excellent weed suppression. In addition, 90 -day ground cover was recorded using the Canopeo (Oklahoma State University) application on an iPad. All plots were harvested to a 3 -inch stubble height. Plots were harvested using a Winterstieger equipped with a forage Cibus F plot harvester reel-type header that collected a 4.8 -foot by 10 -foot swath to calculate total yield. A subsample was collected and dried at $130^{\circ} \mathrm{F}$ until constant weight was achieved to calculate dry matter (DM) concentration.

Forage quality was estimated using NIR (Foss 2500, Foss North America, Eden Prairie, Minnesota) and the mixed hay equation of the NIRS Forage and Feed Testing Consortium (Madison, Wisconsin). Data was used to populate a Nitrogen Availability Calculator Model developed by the University of Georgia College of

Agriculture and Environmental Sciences (Athens, Georgia) to report estimated N availability after 2 weeks, 4 weeks and 3 months after termination.

Economic data (Tables 11 and 12) was calculated using local (Mississippi) retail cost of seed from two sources per variety with that cost added to a fixed planting cost of $\$ 13$ per acre. Nitrogen value was presented as a national average value, and data were analyzed using the General Linear Model (PROC GLM) of SAS and mean separation was conducted using LSD at $\alpha=0.05$.

The plots at Holly Springs were not considered for data collection due to wildlife grazing pressure that led to limited growth by the scheduled harvest date. Data presented in Tables 3-10 can be used to evaluate the performance of each forage crop within its respective trial. Mean and harvest comparisons were evaluated statistically by using the least significant difference (LSD) test at the probability level of $\alpha=0.05$. The LSD value represents the minimum amount of yield (pounds per acre) that must be observed between any two varieties to determine if the difference was due to variety variation alone. Sources of seed are presented in Table 13.

2 Mississippi Cover Crop Variety Trials, 2019

## Results

Total nitrogen (TN) production of the aboveground biomass increased 19\% at Starkville and $27 \%$ at Newton when crop termination was delayed for 2 weeks. In general, legumes like crimson, berseem, balansa, hairy vetch, and winter pea varieties benefited the greatest with respect to TN when termination was delayed. The earliest maturing crop were the radish varieties, which were unaffected by the delay in harvest and were beginning to defoliate by the March 15 termination. In Starkville, ryegrass, rye berseem, and hairy vetch produced the greatest amount of TN by the March 15 termination date. At Newton, winter pea, berseem, and crimson clover produced the greatest TN yield for the earlier termination. Weed suppression was greatest for ryegrass and rye at both locations. Among legume crops, weed suppression was greatest for berseem and hairy vetch at both sites.

When considering variety performance in regards to nitrogen production, results were variable between locations. In Starkville the 'B-18.2014' berseem clover yielded more TN at both termination dates than the other berseem varieties and had greater weed suppression. 'Fixation' produced the greatest TN and weed suppression among balansa clovers by the second termi-
nation date. Though crimson clovers are typically the earliest maturing clovers, weed suppression was only fair among varieties. 'White Cloud' and 'Kentucky Pride' crimson outyielded the other varieties only when termination was delayed 2 weeks. In Starkville, 'Survivor' winter peas produced the greatest TN among winter pea varieties. Among cereal rye varieties 'Wintergrazer 70' and 'Elbon' were the greatest TN producers at both termination dates. At Newton, 'Fixation' and 'GO-FBG' were the greatest TN producers among balansa varieties. 'Frosty' and 'B-18.2014' outyielded 'Balady' berseem clover. 'Dixie' was the greatest TN yielder among crimson varieties by the March 15 termination but was similar to 'White Cloud' and 'Kentucky Pride' 2 weeks later. 'Winter King' hairy vetch was the earliest producer of N but was surpassed by 'Patagonia Inta' by April 1.

When considering the economic value of a cover crop, one can estimate the value of chemical N by the unit N applied and compare that dollar value to the cost of planting and incorporating a cover-crop species. Some added benefits of a cover crop may consider organic matter and N stabilization in the soil. The data presented in Tables 3 and 4 considers only the aboveground biomass and does not include root biomass.

Table 3. Predicted nitrogen availability of cover crop varieties at 2 weeks, 3 weeks, and 3 months after two termination dates in Starkville, Mississippi.

12 Mississippi Cover Crop Variety Trials, 2019

## [STATE <br> MISSISSIPPI STATE <br> U N I V ER S IT Y $\mathbf{T m}_{\text {t }}$

## MS AGRICULTURAL AND FORESTRY EXPERIMENT STATION

The mission of the Mississippi Agricultural and Forestry Experiment Station and the College of Agriculture and Life Sciences is to advance agriculture and natural resources through teaching and learning, research and discovery, service and engagement which will enhance economic prosperity and environmental stewardship, to build stronger communities and improve the health and well-being of families, and to serve people of the state, the region and the world.

Mention of a trademark or proprietary product does not constitute a guarantee or warranty of the product by the Mississippi Agricultural and Forestry Experiment Station and does not imply its approval to the exclusion of other products that also may be suitable.

[^0]:    Recognition is given to student worker Joey Hester for his assistance in cultivating, packing, planting, harvesting, and recording plot data.
    This document was approved for publication as Information Bulletin 542 of the Mississippi Agricultural and Forestry Experiment Station. It was published by the Office of Agricultural Communications, a unit of the Mississippi State University Division of Agriculture, Forestry, and Veterinary Medicine. It is a contribution of the Mississippi Agricultural and Forestry Experiment Station.
